1 Proof of asymptotic behaviour of eigenvalues in families of expanders

The main topic of the seminar is the study of families of expanders in the context of connected, k-regular and finite graphs. A family of expanders consists in a sequence of graphs of increasing size such that the isoperimetric number $h(X)$ satisfies $h(X) \geq \epsilon$ for some fixed positive ϵ and for all graphs X in the sequence. The isoperimetric number, in the context of finite graphs, can be defined as:

$$h(x) = \min\left\{ \frac{|\partial F|}{|F|} \mid F \subseteq V, |F| \leq \frac{n}{2} \right\}$$

Earlier in the seminar, we established that the isoperimetric number is bounded by the spectral gap, in particular,

$$\frac{k - \mu_1}{2} \leq h(x) \leq \sqrt{2k(k - \mu_1)}$$

where μ_1 denotes the first nonzero eigenvalue. Moreover, we showed that the spectral gap cannot grow too much, i.e.

$$\liminf_{m \to +\infty} \mu_1 \geq 2\sqrt{k-1}$$

In this session, we aim to strengthen this result by proving that a non-trivial fraction of the eigenvalues of the graph lies within the interval $[(2-\epsilon)\sqrt{k-1}, k]$ for any given $\epsilon > 0$.

To prove this, we introduce a set of matrices A_r, which are polynomials in the incidence matrix A. The entries of A_r describe the number of backtracking-free paths of length r between two vertices.

After establishing the necessary properties of these polynomials, we compute their generating function which is closely related to teh generating function of Chebyshev polynomials $(U_m)_{m\in\mathbb{N}}$. This fact allows us to prove the following link between the two:

$$\sum_{x\in V}\sum_{0\le r\le \frac{m}{2}}(A_{m-2r})_{xx}=(k-1)^{\frac{m}{2}}\sum_{j=0}^{n-1}U_m\left(\frac{\mu_j}{2\sqrt{k-1}}\right)$$

for all $m\in\mathbb{N}$. Chebishev polynomials will be instrumental in introducing measures in the proof.

The key measure we use is:

$$\nu=\frac{1}{n}\sum_{j=0}^{n-1}\delta_{\frac{\mu_j}{\sqrt{k-1}}}$$

where δ_a is the Dirac measure at a, and $\mu_0,\dots,\mu_{n-1}$ are the eigenvalues of the graph. The Dirac measure δ_a acts as an indicator function of whether a lies in a given interval. Hence, the measure ν counts the number of eigenvalues within a specific range.

We then prove that any measure ν' for which

$$\int_{-L}^{L}U_m\left(\frac{x}{2}\right)d\nu'\ge 0$$

for all m, satisfies that

$$\nu'[2-\epsilon,L]\ge C$$

where C is a constant that only depends on ϵ and L, and is strictly positive.

Finally, we demonstrate that ν satisfies this condition and, with a suitable choice of L, we conclude the desired result.

As an additional result, we show a similar conclusion for the negative eigenvalues of the graph, generalizing an earlier result.
